Authors’ contributions
This work was carried out in collaboration among all authors. Author MAAK wrote, revised and edited the final manuscript and responsible for summarizing all epidemiological and clinical data. Authors KS, AM, AZ and EA collected the data and supported outbreak investigation. All authors read and approved the final manuscript.

ABSTRACT

A lot of coronavirus disease 2019 (COVID-19) related deaths were reported in Yemen about what risk factors contributing to this excess death? Hodeidah governorate at Western part of Yemen exposed to COVID-19 pandemic like other governorates in Yemen, adding to the current chronic diseases’ problems and endemic of vector – borne diseases namely malaria and dengue. The aim of this case report is to explore more data about COVID-19 – dengue fever coinfection related deaths in Hodeidah, Yemen, with both infections cause high mortality rates. The case reported

# Associated Professor in Pharmacology of Infectious, Epidemic Diseases and Tropical Medicine) and scientific consultant on COVID-19 humanitarian project in Hodeidah, Yemen and – Dean of CTMES – HU;

here shows a 25-year-old male, cough, hypoxia, fever 38°C, difficult in breathing, and bleeding from nose as major of symptoms with oxygen saturation (O₂) of 70%, 30 ipm of respiratory rate (RR), 120/80 mmHg of blood pressure, and 120 bpm of heart rate (HR). The patient was diagnosed with bilateral asymmetrical consolidative change with ground glass opacification based X-ray, the leukocytosis, lymphopenia, neutrophilia, and thrombocytopenia were reported. The level of random blood sugar (RBS) was normal, increase in liver enzyme was observed. Mild increase in serum creatinine with C – reactive protein (CRP) was high reactivity with positive COVID-19 and hemorrhagic dengue fever. The patient passed away (death) within two hours in triage. In conclusion, the co-infections with other infection like dengue is of high concern and this is the first reported case of COVID-19 and dengue coinfection presented as stroke and highlights the complex context of diagnostic and therapeutic management in tropical settings such as Hodeidah, Yemen.

Keywords: COVID-19; dengue; Hodeidah; Yemen.

1. INTRODUCTION

Coronavirus disease 2019 (COVID-19) is a respiratory disease caused by a single-stranded positive sense RNA virus that was first isolated in December 2019 after it emerged in Wuhan, China [1,2]. In Yemen, the first case was registered on April 10, 2020 in Hadhramout [3], with further cases later identified in other parts of the country as the disease spread. Hodeidah governorate lies in the western part of Yemen, and has been similarly exposed to the COVID-19 pandemic to other governorates in Yemen, adding to the ongoing chronic challenges in the region. Hodeidah is facing a complex spectrum of determinants of health, including poverty, illiteracy, food insecurity, malnutrition and multiple epidemics as well as humanitarian crises resulting from the armed war that has been ongoing since 2015. At the time of writing, no research has been conducted documenting the COVID-19 pandemic in Hodeidah, especially related to morbidity and mortality. Several other notable disease outbreaks included malaria, dengue fever [4-6], chikungunya [7], west – Nile virus [8], cholera [9], diphtheria [10-11] and measles [12-13] were reported in Hodeidah, Yemen. These are due to a high density of vectors in this region and endemic areas for malaria and dengue, previous study reported high prevalence of malaria – dengue coinfection (37%) [4]. Also, AL Kamarany et al reported 49/505 cases (severe and critical) were confirmed based on RT – PCR [14-16] and 68.05% of Hodeidah people exposure to COVID-19 infection based on immunological method [17]. Therefore, the aim of this case report is to explore more data about COVID-19 – dengue fever coinfection related death in Hodeidah, Yemen.

2. CASE PRESENTATION

The patient was received and assessed directly clinically in triage unit of COVID-19, isolation department, Center of Tropical Medicine and Infectious Diseases (CTMID), AL-Thawrah Public Hospital Authority, Hodeidah, Yemen. A 25-year-old male, cough, hypoxia, fever 38°C, difficult in breathing, bleeding from nose as major of symptoms with 70% of oxygen saturation (O₂), 30 ipm of respiratory rate (RR), 120/80 mmHg of blood pressure, and 120 bpm of heart rate (HR)”. Chest x-ray, complete blood count, C – reactive protein (CRP) were carried out. Also, the nasopharyngeal swab was collected and the COVID-19 was confirmed based on real time – polymerase chain reaction (RT-PCR). In addition, the dengue fever infection was tested based on rapid test (IgM). The patient was diagnosed, bilateral asymmetrical consolidative change with ground glass opacification and the lung involvement more than 50%. Increase in white blood cells (leukocytosis) that was 26000 ±10^9/L, lymphopenia (6%), neutrophilia (90 %), and thrombocytopenia (141 x 10^3 /L) were reported, and a mild increase in hemoglobin (Hct) was 47%. The level of random blood sugar (RBS) was normal (131 mg/dL), increase in liver enzymes (51 unit/L of Alanine transaminase (ALT), and 157 unit/L of Aspartate transferase (AST)). Mild increase in serum creatinine (1.6 mg/dL). On the other mean, increase the neutrophil 90/6 lymphocyte ratio (NLR) that was 15% as predication of severity of case with CRP was high reactivity (43 mg/dL) with positive COVID-19 infection and hemorrhagic dengue fever (coinfection). The patient was died within two hours in triage unit of COVID-19.
The study focused on epidemiological and clinical features of COVID-19 – dengue fever co-infection in Hodeidah, Yemen (while the COVID-19 pandemic takes the world by storm, dengue-endemic regions risk developing a co-epidemic in COVID-19/dengue co-infection). Several cases were emerged in different countries. In Philippines reported a 38-year-old male patient with high-grade fever, with complaints of nausea, joint, and muscle aches, all characteristic symptoms of COVID-19 and dengue but was not severe, although the tests confirmed the infections to be “moderate to severe” and showed steady and rapid recovery [21]. Previous studies in Latin America reported that co-infection with SARS-CoV-2 and dengue virus is associated with worse outcomes with significant morbidity and mortality. The similar clinical and laboratory features of each infection are a challenge in accurately diagnosing and treating cases. Establishing an early diagnosis could be the answer to reducing the estimated significant burden of these conditions” [22]. “Two cases were reported in Maldives. Case 1 was a 39-year-old Asian male, presented on day 6 of dengue infection with warning signs. Case 2 was a 38-year-old Asian male, was admitted on day 5 of illness with symptoms of acute respiratory infection. Evaluation of progressive leukopenia and thrombocytopenia showed positive dengue serology” [23]. Study identified “two pregnancies with dengue and COVID-19 co-infection; one ended with premature rupture of membrane and intrauterine growth restriction fetus, while the other one ended with maternal mortality and intrauterine fetal death. COVID-19 and dengue co-infection had worse outcomes regarding mortality rates, ICU admission, and prolonged hospital stay. Thus, wise-decision management approaches should be adequately offered to these patients to enhance their outcomes. Establishing an early diagnosis might be the answer to reducing the estimated significant burden of these conditions” [24]. “COVID-19 and dengue co-infection was associated with severe disease and fatal outcomes. The correct diagnosis and treatment of co-infection poses a substantial challenge due to the overlapping clinical and laboratory parameters. Therefore, confirmative diagnostic tests are necessary for accurate and timely diagnosis and patient management” [25]. Finally, Old age and comorbidity with non-communicable diseases may be contributing factors to excess deaths among SARS-CoV-2 patients. Co-infections with other

infections like dengue is of high concern in Hodeidah, Yemen [26,27].

4. CONCLUSION

The co-infections with other infection like dengue is of high concern and this is the first reported case of COVID-19 and dengue coinfection presented as stroke and highlights the complex context of diagnostic and therapeutic management in tropical settings such as Hodeidah, Yemen and may be contributing factor to excess deaths.

FUNDING

This study was funded by Center of Tropical Medicine and Infectious Diseases (CTMID), Al-Thawara Public Hospital Authority, Hodeidah, Yemen in collaboration with Health and Nutrition Program, Save the Children International (SCI), Hodeidah Office, Yemen Country and Hayel Saeed Anam Companies Group (HAS). The publication fee is not supported in this fund.

CONSENT

As per international standards or university standards, Participants’ written consent has been collected and preserved in Medical File. The raw data are secured in CTMES – HU and CTMID, Hodeidah, Yemen.

ETHICAL APPROVAL

The studies involving human participants were reviewed and approved by the Ethics Committee of CTMES – HU, Hodeidah, Yemen.

ACKNOWLEDGEMENTS

The authors would like to thank the supervisor and medical staff of the COVID-19 isolation department, Molecular Biology Unit, Center of Tropical Medicine and Infectious Diseases (CTMID), AL Thawara Public Hospital Authority, Hodeidah, Yemen for their fruitful assistance. Also to thank for Dr. Abdultif Magram in Diagnostic Advanced AL Razi Center, Hodeidah, Yemen for supporting the radiological diagnosis.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
